Results of the new EPO-wide model

Fit to **LL_VAST** x lambda= 100 (CV=0.20)

Or

Fit to **PS_VAST** x lambda= 100 (CV=0.20)

Main Index: LL_VAST X 100

Even when the strongest emphasis is given to LL_VAST indices ($\lambda = 100$, $CV=0.2$), the model is not able follow most of the PS_VAST index, almost total mismatch.

Main Index: PS_VAST X 100

Even when the strongest emphasis is given to PS_DEL_VAST ($\lambda = 100$, $CV=0.2$), the model is not able to fit the largest values

The LL indices are not well fit

Year-Año

Data Source: Gridded data

Marks hypothesis:

A 2.5 kg YFT is about 48cm and 1.25 years old.

A 15 kg YFT is about 90cm and 2 years old.

The FO fisheries catch fish that are about 35 cm or larger. 35 cm is about 0.5 years old.

The 1998 cohort would be caught in the small category in 1998 quarter 3 through 1999 quarter 1 (1998 Q3 the cohort is 35 at the start of the quarter, 1999 Q2 is 48cm at the start of the quarter)

The 1999 cohort would be caught in the small category in 1999 quarter 3 through 2000 quarter 1 (1999 Q3 the cohort is 35 at the start of the quarter, 2000 Q2 is 48cm at the start of the quarter)

The 1998 cohort would be caught in the medium category in 1999 quarter 2 through 1999 quarter 4 (at the start or 2000 the cohort would be 90cm)

The 1999 cohort would be caught in the medium category in 2000 quarter 2 through 2000 quarter 4 (at the start or 2001 the cohort would be 90cm)

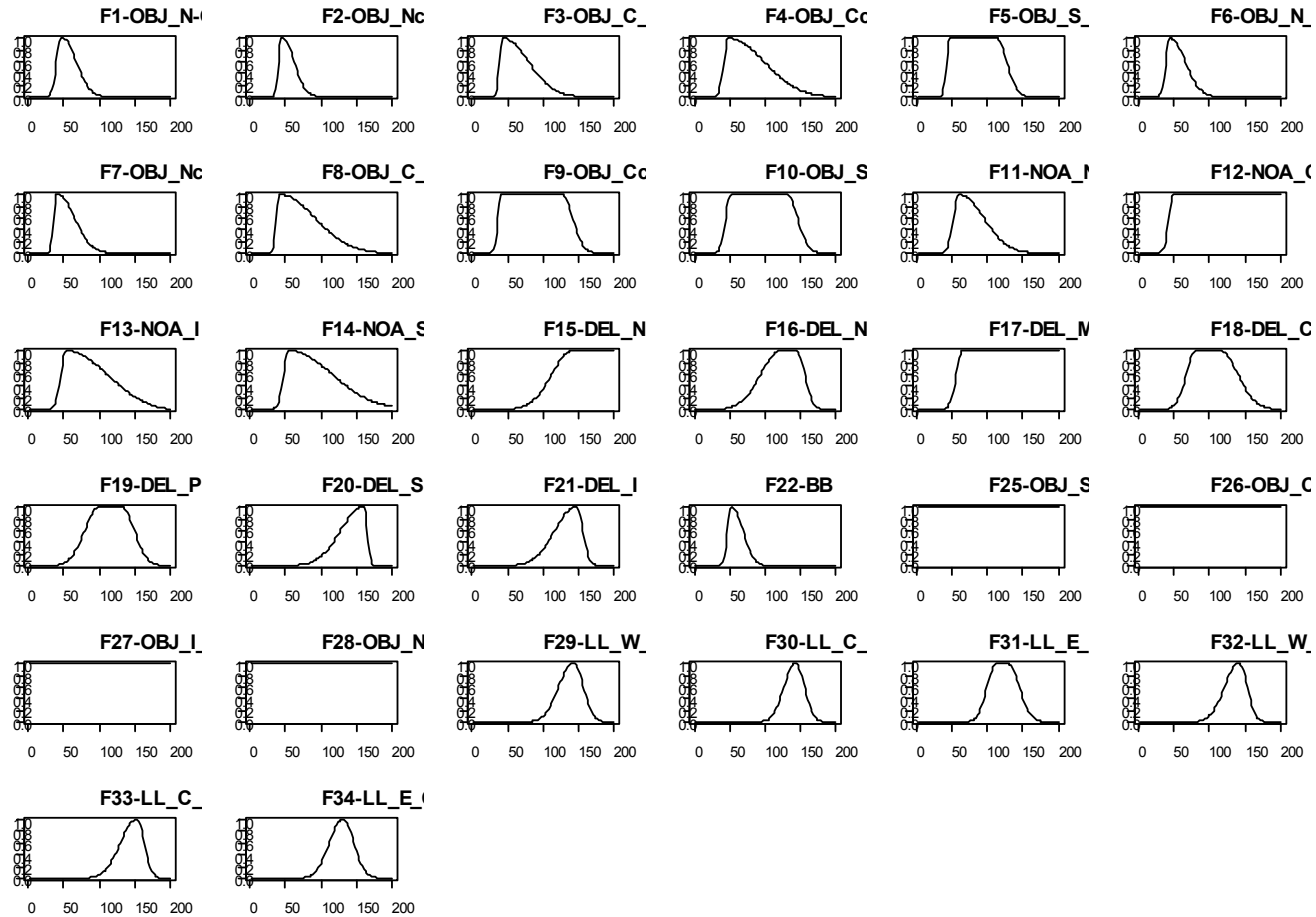

The 1998 cohort would be caught in the Large category in 2000 quarter 1 through 2000 quarter 4 (I just chose 1 year arbitrarily)

The 1999 cohort would be caught in the large category in 2001 quarter 1 through 2001 quarter 4 (I just chose 1 year arbitrarily)
