

ASSESSMENT OF BIGEYE TUNA (*THUNNUS OBESUS*) IN THE EASTERN PACIFIC OCEAN

January 1975 – December 2006

Outline

- Stock assessment
 - Overview of assessment model
 - Fishery data
 - Assumptions
 - Results of base case model
 - Projections
- Sensitivity analyses
- Summary and conclusions
- Discussion

Overview of assessment

- Age-structured, statistical, catch-at-length model (Stock Synthesis II).
- Same type of model as A-SCALA or MULTIFAN-CL
- Differences between SS2 and A-SCALA

Bigeye fishery definitions

**Early FLT (1)
Early & Recent UNA (6, 7)**

**Recent FLT (2-5)
Discards (10-13)**

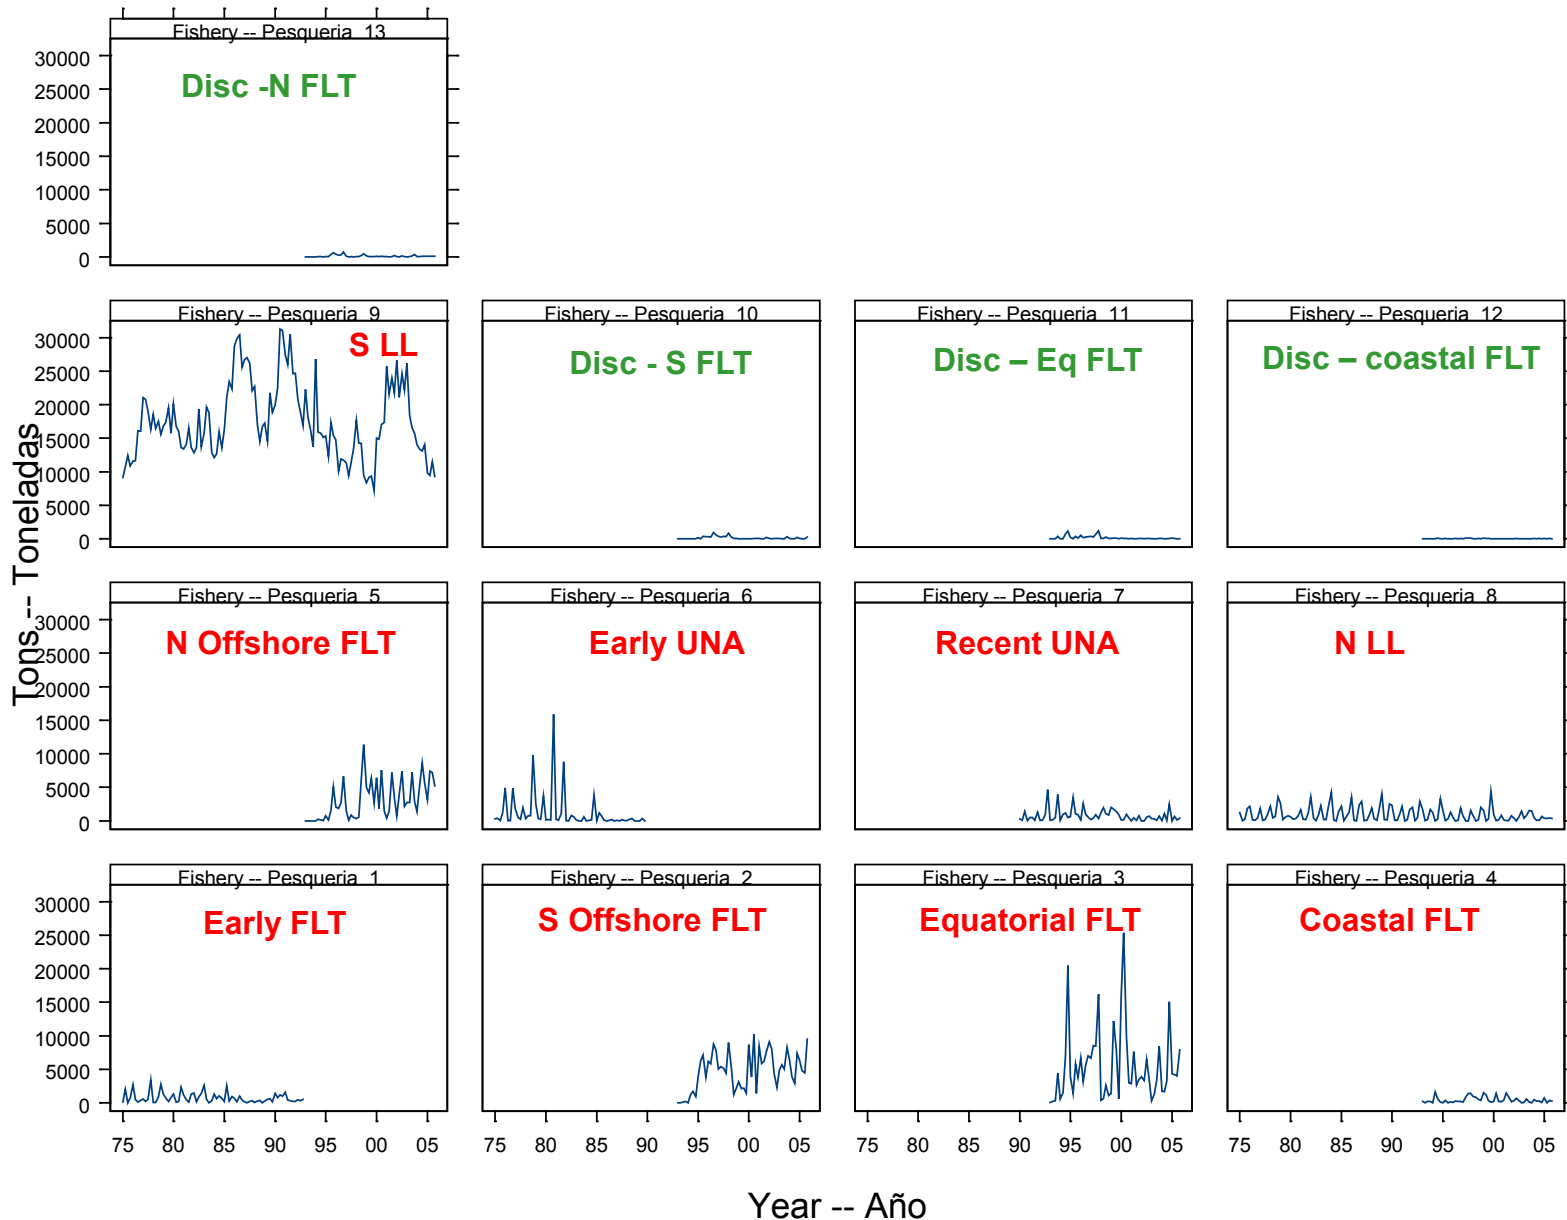

**N Longline (8)
S Longline (9)**

FLT – Floating objects; UNA - Unassociated

Data - catch

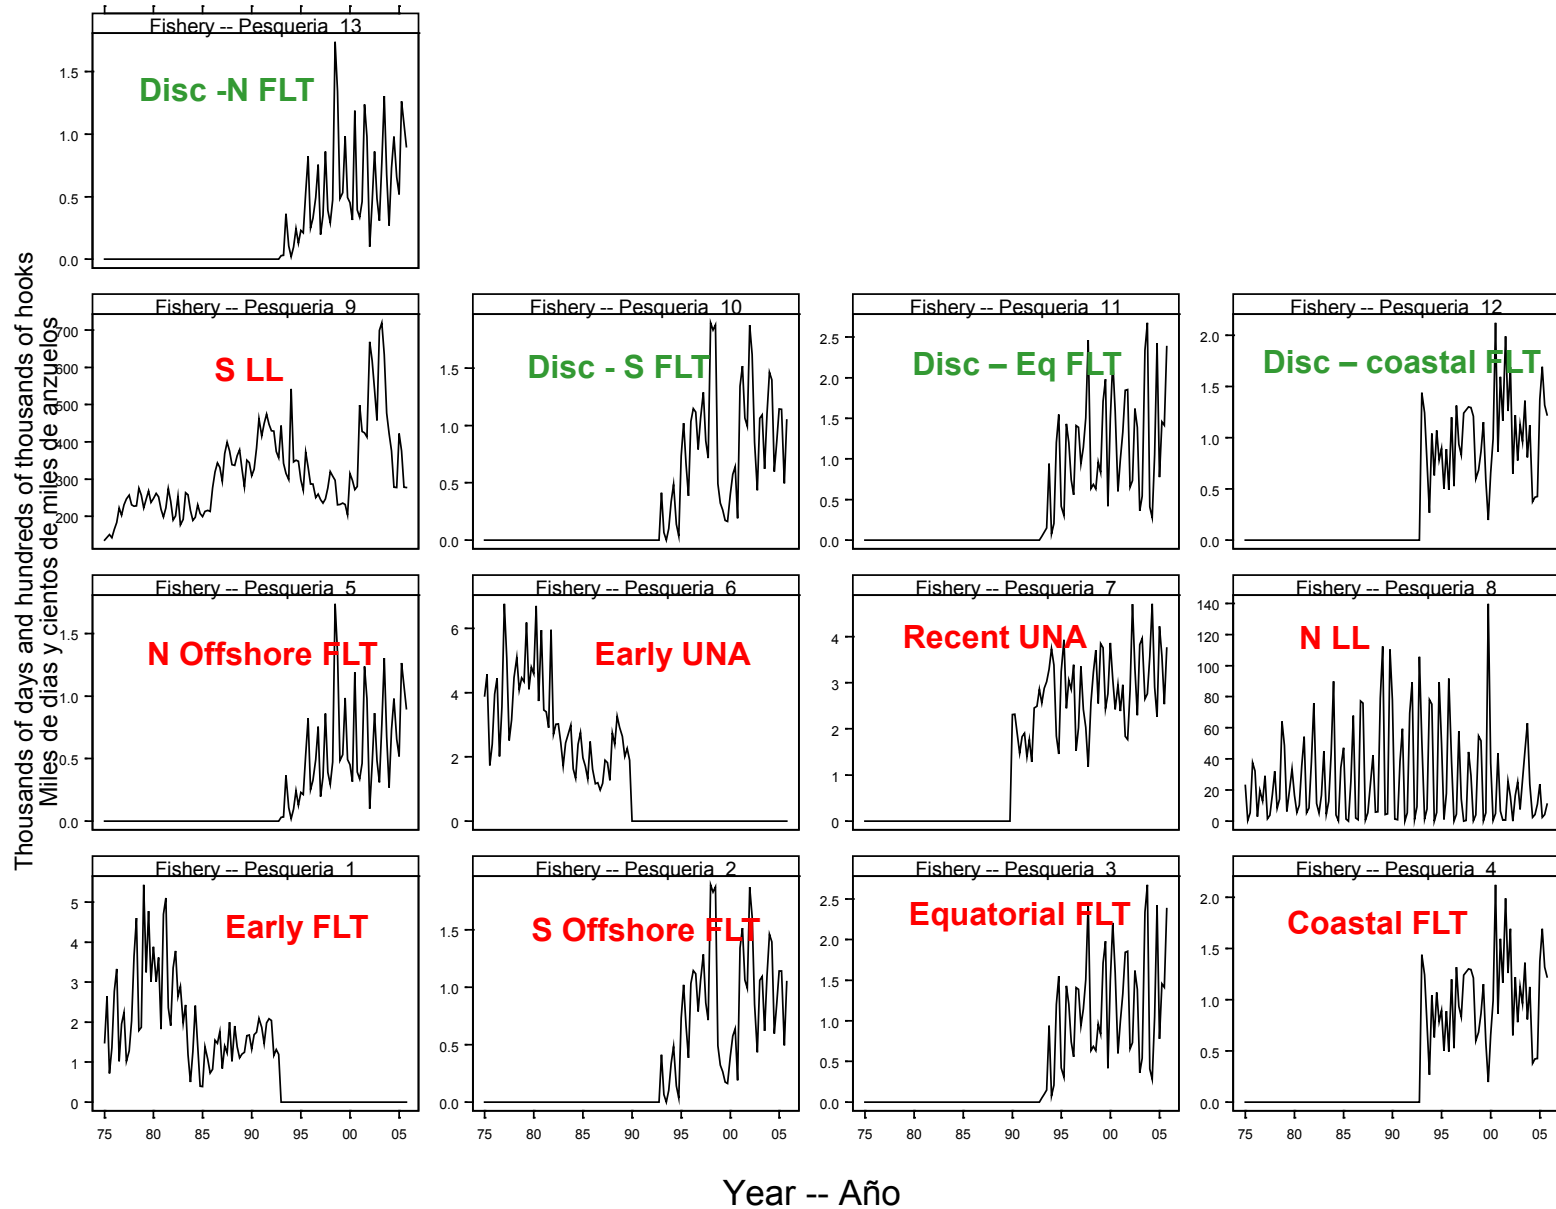

Data - discards

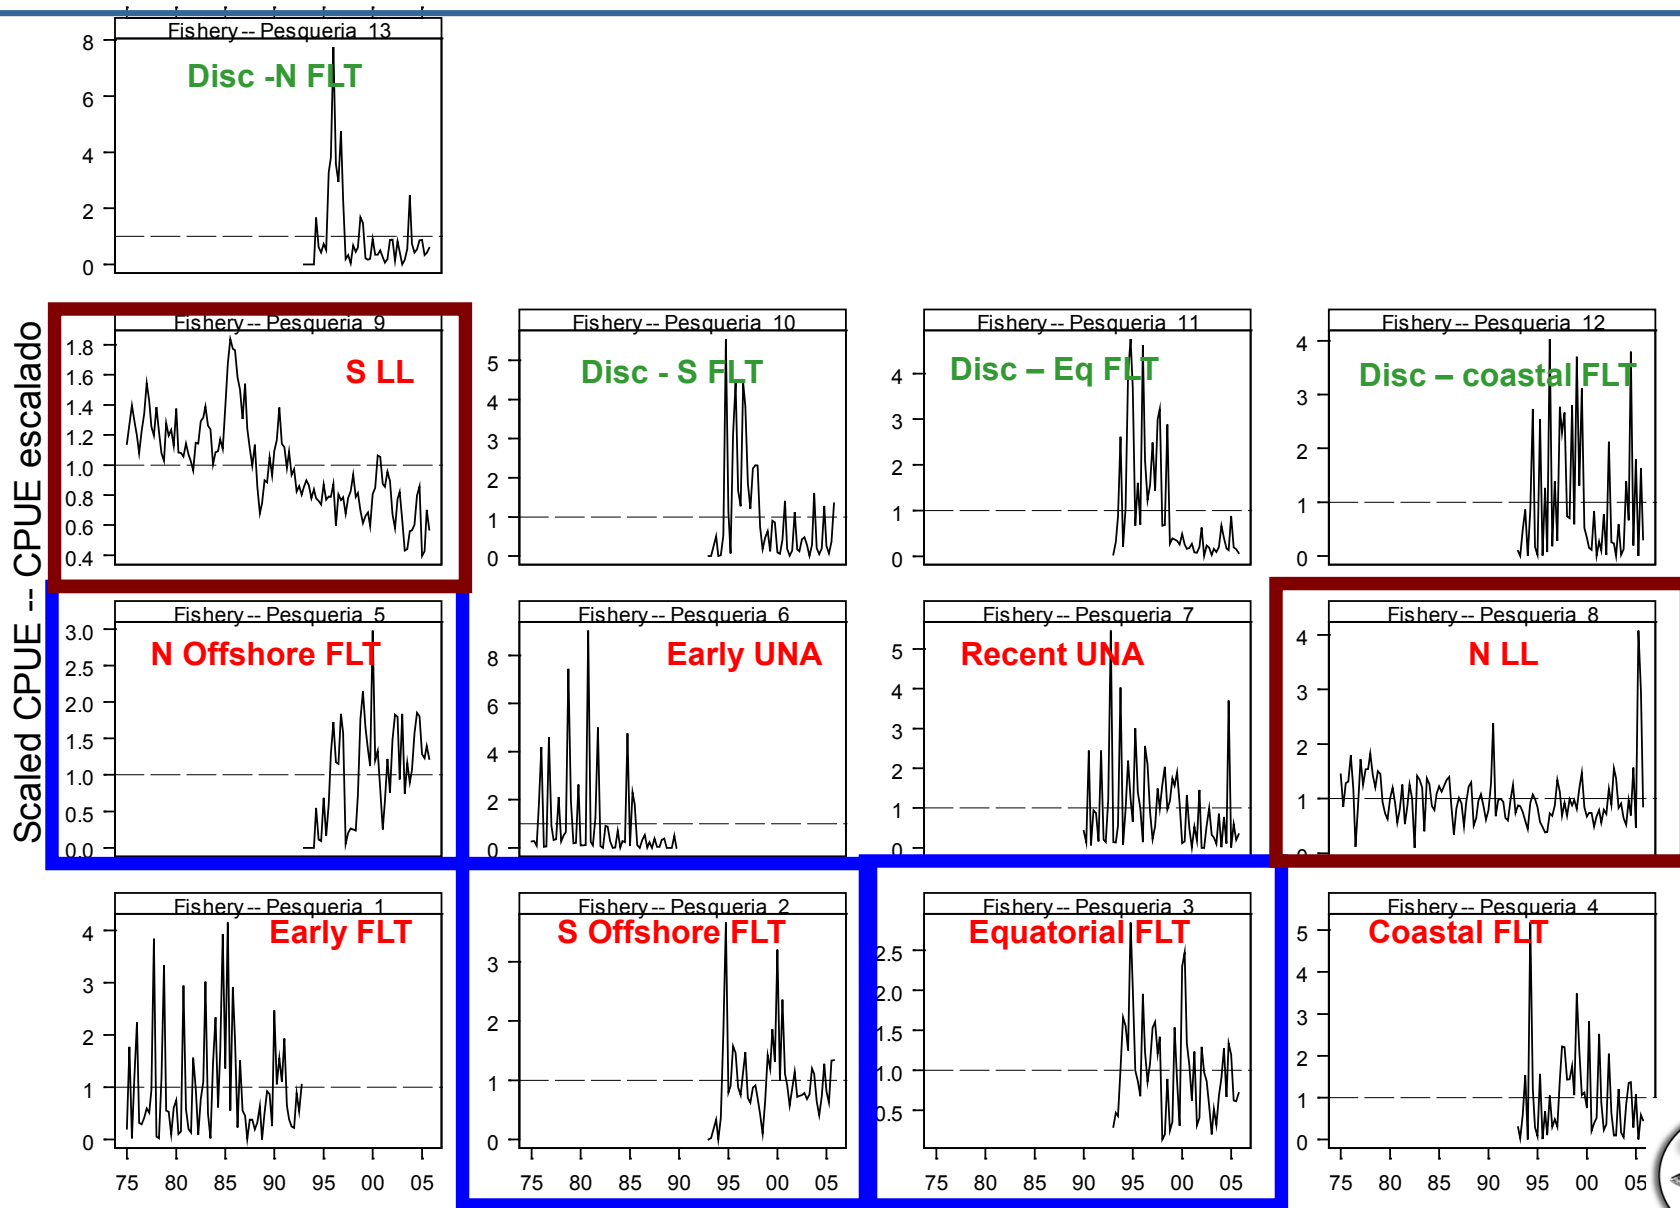

Year -- Año

Data - effort

Data - CPUE

Year -- Año

Data - Length frequency data

Sexes combined whole catch lengths for fleet 3 (max=0.24)

Assumptions (base case) - movement

DATA

- Tagging records indicate little exchange of bigeye between E and W Pacific
- Results from conventional and archival tagging indicate regional fidelity for bigeye in EPO
- Different CPUE trends between EPO and WCP

ASSUMPTIONS

- Single stock of bigeye in EPO
- No net movement of fish between the eastern and western Pacific
- SA for EPO and Pacific wide are consistent

Assumptions (base case) - growth

- Von Bertalanffy – fixed parameters

Assumptions (base case) – M

Assumptions (base case) - cont.

- Age-specific maturity and fecundity indices
- No S-R relationship (steepness = 1)

Results (base case)

- Fit to the length frequency
- Fishing mortality
- Selectivity
- Recruitment
- Biomass

Fit to LF data – Pearson residuals

Combined sex whole catch Pearson residuals for fleet 9 (max=2.76)

Fit to CPUE data – Floating object

Fishery 2

Fishery 3

Fishery 5

Fit to CPUE data – Longline

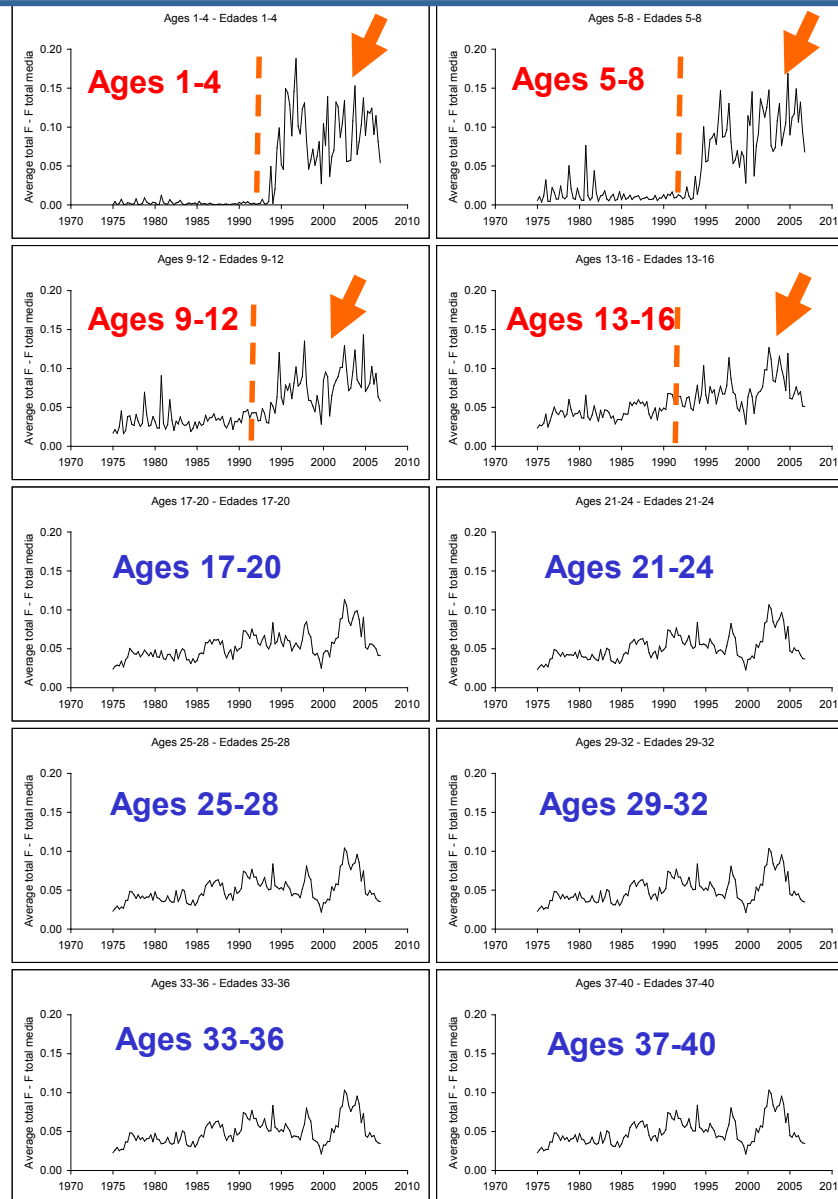

Fishery 8

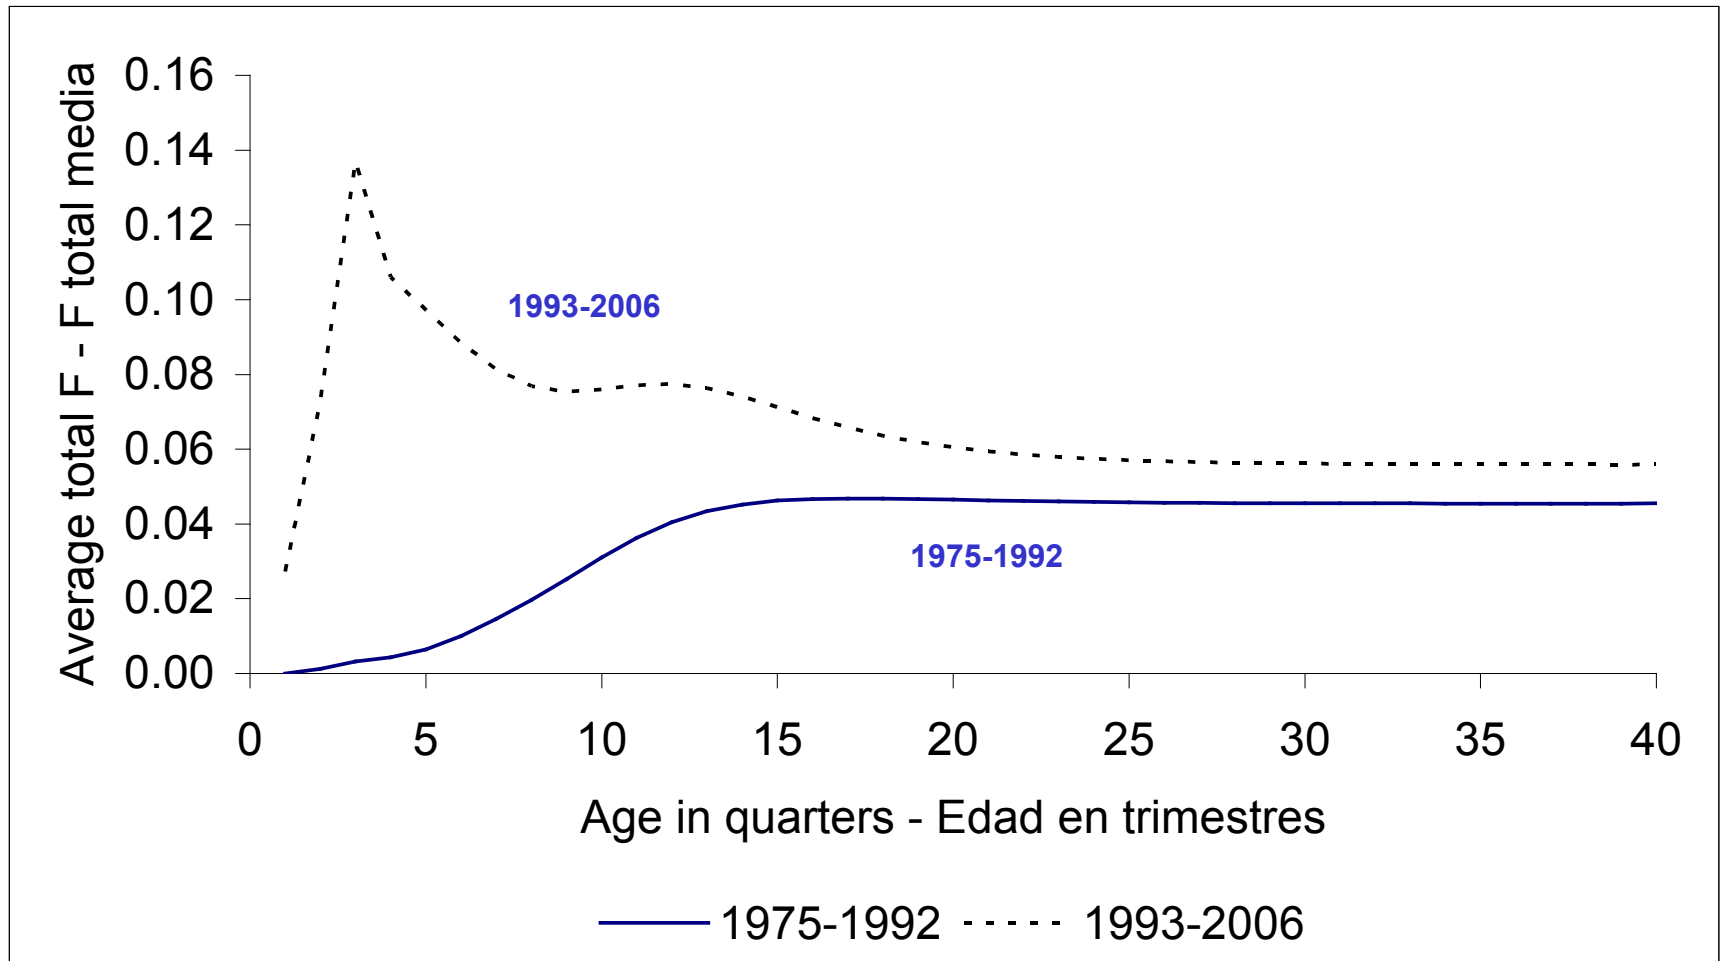

Fishery 9

Forward simulations

- Biomass
- Spawning biomass depletion
- Surface fishery catch
- Longline catch

Spawning biomass ratio

Predicted catches – purse-seine

Surface fisheries

Predicted catches – longline

Longline fisheries

Sensitivity analyses

1. Spawner-recruitment relationship (steepness = 0.75)
2. Growth
 - Growth estimated
 - Linf fixed (171.5 and 201.5)
3. Fitting to the initial equilibrium catch
4. Use of iterative reweighting of data
5. Time blocking of selectivity and catchability for southern longline fishery
6. Inclusion of new Japanese longline data

Stock-recruitment relationship ($h = 0.75$)

iter. rwt	0.23	0.26	0.79
t. blocks	0.25	0.82	1.11
t. blocks (iter. rwt)	0.23	0.26	0.79

Summary: Main results

- Both total and spawning biomass is estimated to have substantially declined since 2000
- Current biomass level is low compared to average unexploited conditions
- The current effort levels are too high to maintain the population at level that will support AMSY
- Yields could be increased if more of the catch was taken in the longline fisheries

What is robust

- Fishing mortality levels are greater than that necessary to achieve the maximum sustainable yield
- Two exceptions: L_{max} fixed and time blocks

Plausible Sensitivities and Uncertainties

- Results are more pessimistic with the inclusion of a stock-recruitment relationship
- Biomass trends are sensitive to the weighting of different datasets
- Recent estimates are uncertain and subject to retrospective bias

Conclusions

- Current spawning biomass is unlikely to remain at or above the level required to produce AMSY.
- In the most recent years the fishing mortality is greater than that required to produce AMSY.
- Under average recruitment, the stock is predicted to be below the level that would support AMSY unless fishing mortality levels are reduced further than the current restrictions.
